Lecture 04 — More Swift Developing Applications for iOS

1

Stride

Floating point

Floating point numbers don't stride by Int, they stride by a floating point value. So 0.5...15.25 is just a Range, not a CountableRange (which is needed for for in).

Luckily, there's a global function that will create a sequence from floating point values!

```
for i in stride(from: 0.5, through: 15.25, by: 0.3) {
```

}

CS193p Fall 2017-18

6

Tuples

What is a tuple?

It is nothing more than a grouping of values. (contain one or more types) Tuples are passed by value, not reference you can use a type.

let x: (String, Int, Double) = ("hello", 5, 0.85) // the type of x is "a tuple" let (word, number, value) = x // this names the tuple elements when <u>accessing</u> the tuple

Tuples

What is a tuple?

```
let x: (String, Int, Double) = ("hello", 5, 0.85) // the type of x is "a tuple"

let (word, number, value) = x // this names the tuple elements when accessing the tuple

print(word) // prints hello

print(number) // prints 5

print(value) // prints 0.85

... or the tuple elements can be named when the tuple is declared (this is strongly preferred) ...

let x: (w: String, i: Int, v: Double) = ("hello", 5, 0.85)

print(x.w) // prints hello

print(x.i) // prints 5

print(x.v) // prints 0.85

let (wrd, num, val) = x // this is also legal (renames the tuple's elements on access)
```

8

Tuples

Tuples as return values

You can use tuples to return multiple values from a function or method ...

```
return (250, 80)
}
let x = getSize()
print("weight is \(x.weight)") // weight is 250
... or ...
print("height is \(getSize().height)") // height is 80
```

CS193p

ACCESS CONTROL

10

Access Control

Protecting our internal implementations

Likely most of you have only worked on relatively small projects
Inside those projects, any object can pretty much call any function in any other object
When projects start to get large, though, this becomes very dicey
You want to be able to protect the INTERNAL implementation of data structures

You do this by marking which API* you want other code to use with certain keywords

* i.e. methods and properties

CS193p

Access Control

Protecting our internal implementations

Swift supports this with the following access control keywords ...
internal - this is the default, it means "usable by any object in my app or framework"
private - this means "only callable from within this object"
private(set) - this means "this property is readable outside this object, but not settable"
fileprivate - accessible by any code in this source file

CS193p Fall 2017-18

12

Access Control

Protecting our internal implementations

Swift supports this with the following access control keywords \dots

internal - this is the default, it means "usable by any object in my app or framework" private - this means "only callable from within this object"

private(set) - this means "this property is readable outside this object, but not settable' fileprivate - accessible by any code in this source file

public - (for frameworks only) this can be used by objects outside my framework open - (for frameworks only) public and objects outside my framework can subclass this

Fall 2017-18

Access Control

Protecting our internal implementations

Swift supports this with the following access control keywords ...

internal - this is the default, it means "usable by any object in my app or framework"

fileprivate - accessible by any code in this source file

public - (for frameworks only) this can be used by objects outside my framework

open - (for frameworks only) public and objects outside my framework can subclass this

We are not going to learn to develop frameworks this quarter, so we are only concerned

private, private(set), fileprivate and internal (which is the default, so no keyword)

15

Access Control

Protecting our internal implementations

Swift supports this with the following access control keywords ...

internal - this is the default, it means "usable by any object in my app or framework"

private(set) - this means "this property is readable outside this object, but not settable" fileprivate - accessible by any code in this source file

A good strategy is to just mark everything private by default.

Then remove the private designation when that API is ready to be used by other code.

```
private lazy var game:MatchingGame = MatchingGame(numberOfPairsOfCards: numberOfPairsOfCards)

private(set) var numberOfPairsOfCards:Int{
    return (cardButtons.count+1)/2
}

private lazy var game:MatchingGame = MatchingGame(numberOfPairsOfCards: numberOfPairsOfCards)

private var numberOfPairsOfCards:Int{
    return (cardButtons.count+1)/2
}

private lazy var game:MatchingGame = MatchingGame(numberOfPairsOfCards: numberOfPairsOfCards)

var numberOfPairsOfCards:Int{
    return (cardButtons.count+1)/2
}
```

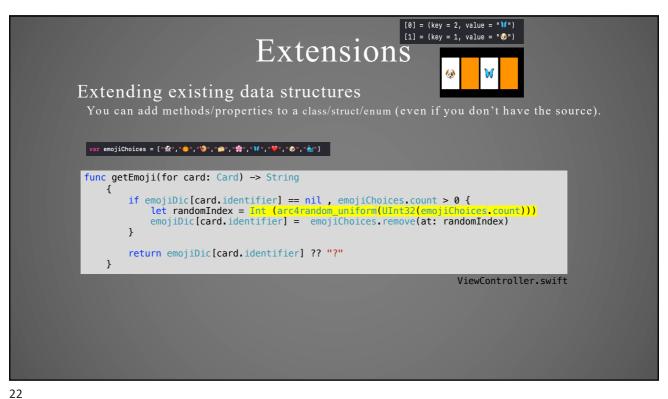

```
private(set) var flipCount:Int = 0
{
    didSet{
        flipCountLabel.text = "Flips: \(flipCount)"
}
}

@IBOutlet private var cardButtons: [UIButton]!
@IBOutlet private week var flipCountLabel: UILabel!

@IBAction private func touchCard(_ sender: UIButton) {
    if let cardNumber = cardButtons.index(of: sender){
        print("cardNumber = \((string(describing: cardNumber))"))
        game.chooseCard(at: cardNumber)
        updateViewFromModel()
        //flipCard(withEmoji: emojiChoices[cardNumber], on: sender)
    }
}else{
    print("not in the collection")
}
flipCount += 1
}
```

```
private func updateViewFromModel()
    for index in cardButtons.indices {
       let button = cardButtons[index]
       let card = game.cards[index]
       if card.isFaceUp{
           button.setTitle(emoji(for: card), for: UIControl.State.normal)
           button.backgroundColor = card.isMatched ? ▼:
       }else{
           button.setTitle("", for: UIControl.State.normal)
           button.backgroundColor =
private var emoji = [Int:String]()
private func emoji(for card: Card) -> String{
   if emoji[card.identifier] == nil, emojiChoices.count>0{
       let randomIndex = Int(arc4random_uniform(UInt32(emojiChoices.count)))
       //emoji[card.identifier] = emojiChoices[randomIndex]
        emoji[card.identifier] = emojiChoices.remove(at: randomIndex)
   return emoji[card.identifier] ?? "?"
```

Extensions Extending existing data structures You can add methods/properties to a class/struct/enum (even if you don't have the source). Let's add a simple extension in Concentration ... CS193p Fall 2017-18

```
Extensions
Extending existing data structures
 You can add methods/properties to a class/struct/enum (even if you don't have the
 func getEmoji(for card: Card) -> String
           if emojiDic[card.identifier] == nil , emojiChoices.count > 0 {
    let randomIndex = Int (arc4random_uniform(UInt32(emojiChoices.count)))
    emojiDic[card.identifier] = emojiChoices.remove(at: randomIndex)
           return emojiDic[card.identifier] ?? "?"
                                                                                   ViewController.swift
 extension Int{
          var arc4random: Int{
               return Int (arc4random_uniform(UInt32(emojiChoices.count)))
```

Computed Properties

The value of a property can be computed rather than stored

```
var foo: Double
A computed property looks like this ...
var foo: Double {
    get {
        // return the calculated value of foo
    }
    set(newValue) {
        // do something based on the fact that foo has changed to newValue
    }
}
```

You don't have to implement the set side of it if you don't want to.

A typical stored property looks something like this ...

The property then becomes "read only".

CS193p Fall 2017-1

24

Extensions

Extending existing data structures

You can add methods/properties to a class/struct/enum (even if you don't have the source).

```
let x = 5.arc4random  // 0, 1, 2, 3, 4

func getEmoji(for card: Card) -> String
{
    if emojiDic[card.identifier] == nil , emojiChoices.count > 0 {
        let randomIndex = emojiChoices.count.arc4random
        emojiDic[card.identifier] = emojiChoices.remove(at: randomIndex)
    }
    return emojiDic[card.identifier] ?? "?"
}

extension Int{
    var arc4random: Int{
        return Int (arc4random_uniform(UInt32(emojiChoices.count)))
    }
}
```

Extending existing data structures You can add methods/properties to a class/struct/enum (even if you don't have the source). func getEmoji(for card: Card) -> String { if emojiDic[card.identifier] == nil , emojiChoices.count > 0 { let randomIndex = emojiChoices.count.arc4random emojiDic[card.identifier] = emojiChoices.remove(at: randomIndex) } return emojiDic[card.identifier] ?? "?" } gxtension Int{ var arc4random: Int{

return Int (arc4random_uniform(UInt32(self)))

26

```
extension Int{
    var arc4random:Int{
        if self>0{
            return Int(arc4random_uniform(UInt32(self)))
        }else if self<0{
            return -Int(arc4random_uniform(UInt32(abs(self))))
        }
        else{
            return 0
        }
    }
}</pre>
```

Extensions

Extending existing data structures

You can add methods/properties to a class/struct/enum (even if you don't have the source).

There are some restrictions

You can't re-implement methods or properties that are already there (only add new ones). The properties you add can have no storage associated with them (computed only).

CS193p Fall 2017-1

Extensions

Extending existing data structures

You can add methods/properties to a class/struct/enum (even if you don't have the source).

There are some restrictions

You can't re-implement methods or properties that are already there (only add new ones). The properties you add can have no storage associated with them (computed only).

This feature is easily abused

It should be used to add clarity to readability not obfuscation!

Don't use it as a substitute for good object-oriented design technique.

Best used (at least for beginners) for very small, well-contained helper functions.

Can actually be used well to organize code but requires architectural commitment.

When in doubt (for now), don't do it

CS193p Fall 2017-18

30

Optionals

Optional

A completely normal type in Swift

It's an enumeration

Let's take a moment and learn about enumerations and then we'll look at Optionals a little closer

CS193p all 2017-18

32

enum

Another variety of data structure in addition to struct and class

It can only have discrete states ...

```
enum FastFoodMenultem {
    case hamburger
    case fries
    case drink
    case cookie
```

An enum is a VALUE TYPE (like struct), so it is copied as it is passed around

CS193p

Enum Associated Data Each state can (but does not have to) have its own "associated data" ... enum FastFoodMenuItem { case hamburger(numberOfPatties: Int) case fries(size: FryOrderSize) case drink(String, ounces: Int) // the unnamed String is the brand, e.g. "Coke" case cookie } Note that the drink case has 2 pieces of associated data (one of them "unnamed") In the example above, FryOrderSize would also probably be an enum, for example ... enum FryOrderSize { case large case small }

34

```
enum FastFoodMenuItem {
    case hamburger(numberOfPatties: Int)
    case fries(size: FryOrderSize)
    case drink(String, ounces: Int) // the unnamed String is the brand, e.g. "Coke"
    case cookie
}
enum FryOrderSize {
    case large
    case small
}
```

CS193p Fall 2017-18

Setting the value of an enum

Just use the name of the type along with the case you want, separated by dot ...

```
case hamburger(numberOfPatties: Int)
  case fries(size: FryOrderSize)
  case drink(String, ounces: Int) // the unnamed String is the brand, e.g. "Coke"
  case cookie
}

let menuItem: FastFoodMenuItem = FastFoodMenuItem.hamburger(numberOfPatties: 2)
var otherItem: FastFoodMenuItem = FastFoodMenuItem.cookie
```

CS193p all 2017-18

37

enum

Setting the value of an enum

When you set the value of an enum you must provide the associated data (if any) ...

let menultem: FastFoodMenultem = FastFoodMenultem.hamburger(numberOfPatties: 2)

var otherItem: FastFoodMenultem = FastFoodMenultem cookie

CS193p all 2017-18

38

enum

Setting the value of an enum

Swift can infer the type on one side of the assignment or the other (but not both) ...

var other Item: FastFood MenuItem = FastFood MenuItem.hamburger(number Of Patties: 2)

var yetAnotherItem = .cookie // Swift can't figure this out

CS193p

```
Checking an enum's state

An enum's state is checked with a switch statement ...

var menultem = FastFoodMenuItem.hamburger(numberOfPatties: 2)

switch menuItem {

    case FastFoodMenuItem.hamburger:
        print("burger")

    case FastFoodMenuItem.fries:
        print("fries")

    case FastFoodMenuItem.drink:
        print("drink")

    case FastFoodMenuItem.cookie:
        print("cookie")

}

Note that we are ignoring the "associated data" above ... so far ...
```

```
Checking an enum's state

An enum's state is checked with a switch statement ...

var menultem = FastFoodMenultem.hamburger(numberOfPatties: 2)

switch menultem {

    case FastFoodMenultem.hamburger:
        print("burger")

    case FastFoodMenultem.fries:
        print("fries")

    case FastFoodMenultem.drink:
        print("drink")

    case FastFoodMenultem.cookie:
        print("cookie")

}

CSIP3p
Fall 2017-18
```

Checking an enum's state An enum's state is checked with a switch statement ... var menultem = FastFoodMenuItem.hamburger(numberOfPatties: 2) switch menuItem { case FastFoodMenuItem.hamburger: print("burger") case FastFoodMenuItem.fries: print("fries") case FastFoodMenuItem.drink: print("drink") case FastFoodMenuItem.cookie: print("cookie") } CS193p Fall 2017-18

42

Checking an enum's state An enum's state is checked with a switch statement ... var menultem = FastFoodMenuItem.hamburger(numberOfPatties: 2) switch menultem { case .hamburger: print("burger") case .fries: print("fries") case .drink: print("drink") case .cookie: print("cookie") } It is not necessary to use the fully-expressed FastFoodMenuItem.fries inside the switch (since Swift can infer the FastFoodMenuItem part of that)

```
break

If you don't want to do anything in a given ease, use break ...

var menultem = FastFoodMenultem.hamburger(numberOfPatties: 2)

switch menultem {

    case .hamburger: break

    case .fries: print("fries")

    case .drink: print("drink")

    case .cookie: print("cookie")
}

This code would print nothing on the console
```

```
default

You must handle ALL POSSIBLE CASES (although you can default uninteresting cases) ...

var menultem = FastFoodMenuItem.cookie

switch menuItem {
    case .hamburger: break
    case .fries: print("fries")
    default: print("other")
}
```

default You must handle ALL POSSIBLE CASES (although you can default uninteresting cases) ... var menultem = FastFoodMenultem.cookie switch menultem { case .hamburger: break case .fries: print("fries") default: print("other") } If the menultem were a cookie, the above code would print "other" on the console

46

Enum Multiple lines allowed Each case in a switch can be multiple lines and does NOT fall through to the next case ... var menultem = FastFoodMenultem.fries(size: FryOrderSize.large) switch menultem { case .hamburger: print("burger") case .fries: print("yummy") print("fries") case .drink: print("drink") case .cookie: print("cookie") } The above code would print "yummy" and "fries" on the console, but not "drink"

CS103p Fall 2017-18

What about the associated data?

Associated data is accessed through a switch statement using this let syntax ...

var menuItem = FastFoodMenuItem.drink("Coke", ounces: 32)

switch menuItem {

 case .hamburger(let pattyCount):

 print("a burger with \(pattyCount) patties!")

 case .fries(let size):

 print("a \(size) order of fries!")

 case .drink(let brand, let ounces):

 print("a \(ounces)oz \(brand)")

 case .cookie: print("a cookie!")

}

49

enum

What about the associated data?

```
Associated data is accessed through a switch statement using this let syntax ...
```

```
var menultem = FastFoodMenultem.drink("Coke", ounces: 32)
switch menultem {
    case .hamburger(let pattyCount): print("a burger with \(pattyCount) patties!")
    case .fries(let size): print("a \(size) order of fries!")
    case .drink(let brand, let ounces): print("a \(ounces)oz \(brand)")
    case .cookie: print("a cookie!")
}
```

The above code would print "a 32oz Coke" on the console

CS193p Fall 2017-18

50

enum

What about the associated data?

```
Associated data is accessed through a switch statement using this let syntax ...
```

```
switch menuItem = FastFoodMenuItem.drink("Coke", ounces: 32)
switch menuItem {
    case .hamburger(let pattyCount): print("a burger with \(pattyCount) patties!")
    case .fries(let size): print("a \(size) order of fries!")
    case .drink(let brand, let ounces): print("a \(ounces)oz \(brand)")
    case .cookie: print("a cookie!")
}
```

Note that the local variable that retrieves the associated data can have a different name (e.g. pattyCount above versus numberOfPatties in the enum declaration)

(e.g. brand above versus not even having a name in the enum declaration)

CS193p

Methods yes, (stored) Properties no An enum can have methods (and computed properties) but no stored properties ... enum FastFoodMenuItem { case hamburger(numberOfPatties: Int) case fries(size: FryOrderSize) case drink(String, ounces: Int) case cookie func isIncludedInSpecialOrder(number: Int) -> Bool { } var calories: Int { // calculate and return caloric value here }

An enum's state is entirely which case it is in and that case's associated data.

CS 193p Fall 2017-18

52

enum

Methods yes, (stored) Properties no

In an enum's own methods, you can test the enum's state (and get associated data) using self ...

CS193p all 2017-18

enum

Methods yes, (stored) Properties no

In an enum's own methods, you can test the enum's state (and get associated data) using self \dots

Special order 1 is a single patty burger, 2 is a double patty (3 is a triple, etc.?!)

CS193p Fall 2017-1

54

enum

Methods yes, (stored) Properties no

In an enum's own methods, you can test the enum's state (and get associated data) using self ...

Notice the use of $_$ if we don't care about that piece of associated data.

CS193p Fall 2017-18

Modifying self in an enum You can even reassign self inside an enum method ... enum FastFoodMenuItem { ... mutating fune switchToBeingACookie() { self = .cookie // this works even if self is a .hamburger, .fries or .drink } CSIO36 Fall 2017-18

56

###
